Gas → Bund Curve

Do European gas prices drive, and predict, moves on the German yield curve through inflation expectations and ECB rate-hike expectations? A plain-language recap of the data, the tests and what they mean. Prepared 11 October 2026; data to the 9 October 2026 close.

1. The answer in one page

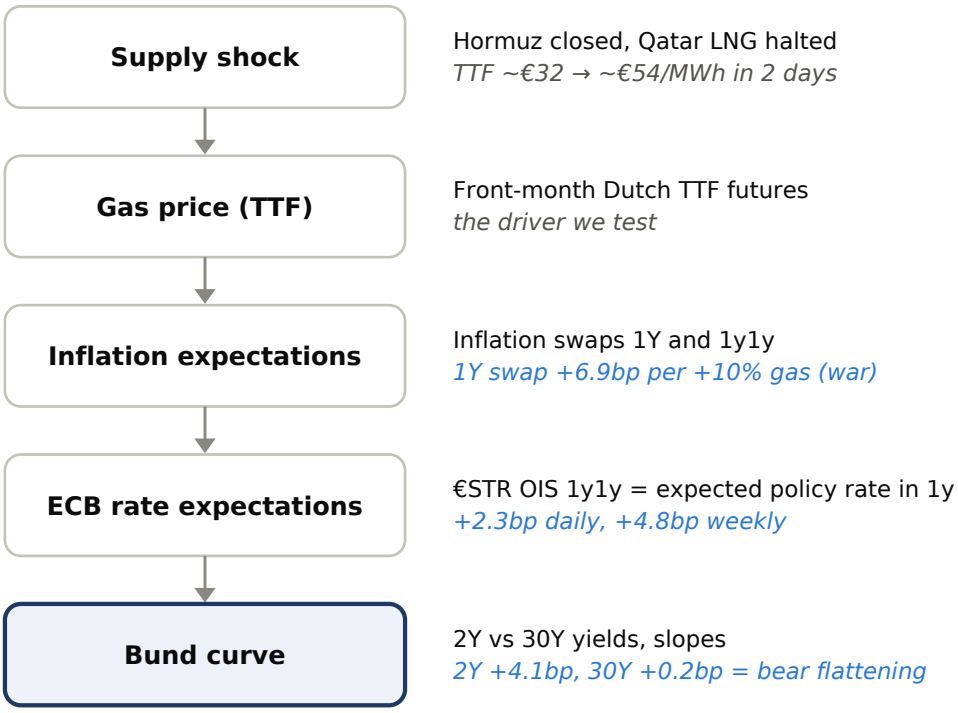

> **Since the Iran war started (2 March 2026), a +10% move in European gas has lifted the German 2-year yield by about 4bp on the same day while leaving the 30-year almost unchanged.** Gas has been a driver of ECB rate-hike pricing and of curve **bear flattening**. This link exists only in the current regime: in 2021-22 it ran the other way, and in normal times it is close to zero.

Link in the chain	What we found (per +10% TTF gas move)	Verdict
1. Gas → realised inflation	~0 on impact; +0.21pp of euro-area inflation (y/y) 9 months later (p = 0.020), +0.24pp after 12. Oil acts at once: +0.30pp the same month.	Yes, with a lag
2. Gas → inflation expectations	1-year inflation swap +6.9bp same day in the war (p < 0.001), vs +1.6bp in 2023-26. The 1y1y forward moves less: +1.8bp.	Yes, amplified in the war
3. → ECB rate expectations	Expected policy rate in one year (€STR OIS 1y1y) +2.3bp daily, +4.8bp weekly. A break test dates the change to 2026-03-05 without being told the war date.	Yes, in the war
4. → Bund curve	Bund 2Y +4.1bp (p = 0.003), Bund 30Y +0.2bp (not significant), 2s30s slope -3.9bp.	Yes: bear flattening
Which flattener	All six slopes flatten. 2s30s largest (-3.9bp daily, -3.0bp weekly). 2s10s and 2s5s react to gas but not to oil.	2s10s purest, 2s30s largest
Regime dependence	Bund 2Y -1.2bp in 2021-22, ~0 in normal times, +4.1bp in the war. War vs normal difference p = 0.004.	Strong
Predicting later curve moves	No drift after day 1-2, no lead in Granger tests, no out-of-sample gain for Bunds.	No

- **Main caveats.** The war regime is short (143 trading days, 32 weeks). Oil moves with gas (correlation 0.69 in the war) and matters even more for inflation pricing.
- **What it means for you.** Treat gas as a regime-dependent front-end driver: watch the rolling sensitivity, because the sign of the link depends on how the market expects the ECB to react.

2. The economic story

The thesis is a chain. Each link must hold for gas to move the Bund curve, and each one was tested separately. The diagram shows the chain with what was measured at every step.

A fifth path runs in parallel: gas reaches realised inflation 6-12 months later, through retail energy bills. Markets anticipate it, which is why links 2 to 4 happen on the day.

Link 1: gas → realised inflation

Gas sets the marginal price of electricity in Europe and feeds household gas bills, fertiliser, chemicals and industry. Retail tariffs are regulated or contracted, so they reset slowly. The effect on the inflation the ECB targets arrives months after the wholesale move.

Link 2: inflation → inflation expectations

Investors do not wait for the inflation prints. They price future inflation today through inflation swaps. The 1-year swap reflects next year's price level. The 1y1y forward reflects inflation one to two years ahead, the horizon the ECB cares about.

Link 3: inflation expectations → ECB rate expectations

A central bank targeting 2% is expected to hike when inflation expectations rise. The market writes the expected path into €STR overnight index swaps (OIS). This link only works if the market *believes* the ECB will react, and that belief is what changed between 2022 and 2026.

Link 4: ECB expectations → the Bund curve

The 2-year Bund mostly reflects the expected ECB path over two years. The 30-year mostly reflects long-run growth, long-run inflation and a term premium. A policy shock therefore lifts the short end more than the long end: yields rise and the curve flattens, a **bear flattening**.

The 2026 context

The ECB hiked in June (deposit rate 2.00% to 2.25%) and September (to 2.50%), its first hikes since 2023. Euro-area inflation reached 3.3% in August, with energy at +14.3%. Between 27 February and 9 October 2026 the Bund 2Y rose from 2.03% to 3.09% and the 30Y from 3.36% to 3.85%.

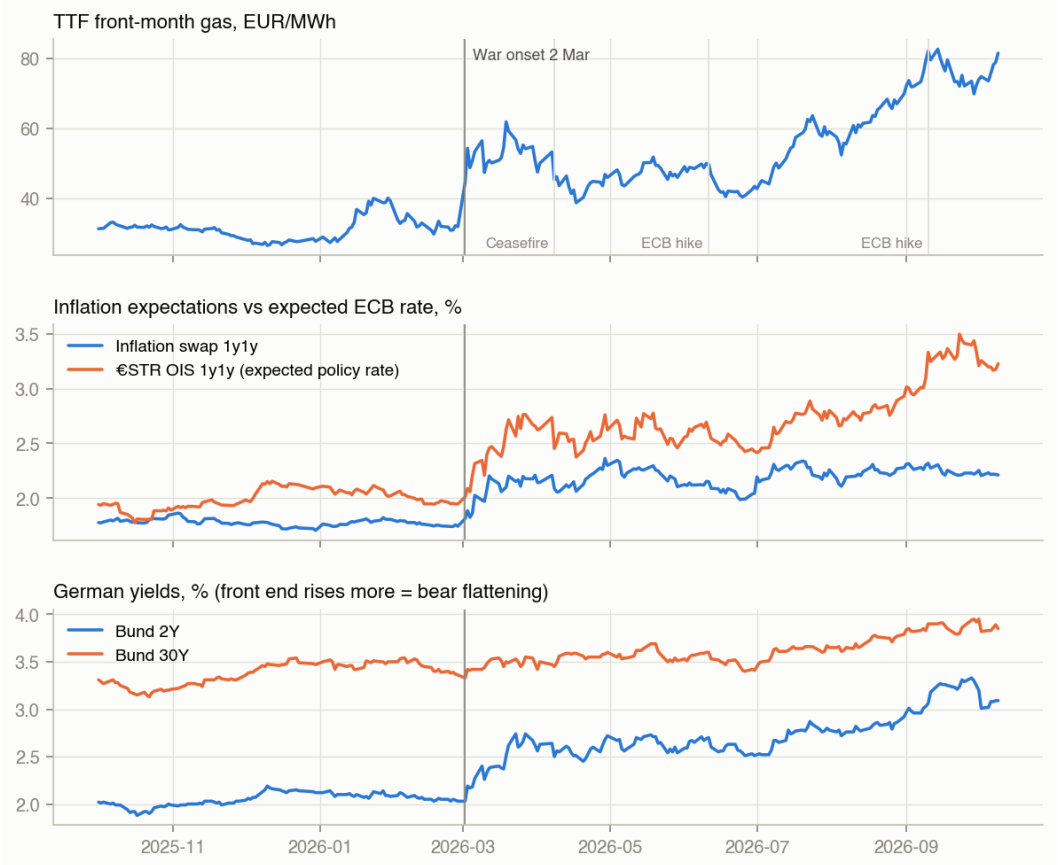

Figure 1. Gas, inflation expectations, expected ECB rate and Bund yields, Oct 2025 to Oct 2026. Vertical line: war onset (2 March 2026).

3. The instruments, in plain words

Each benchmark was chosen for the job it does in the chain. The clean variable name is the column name in the data files.

Instrument (clean name)	What it is	Why this one
TTF front-month gas_ttf_m1_eurmwh	Futures price of Dutch TTF gas for delivery next month, EUR per MWh (LSEG TFMBMc1).	The euro-area wholesale gas benchmark, quoted in euros, the most liquid European gas contract.
Brent front-month oil_brent_m1_usdbbl	Futures price of North Sea crude oil, USD per barrel (LCOc1).	Control: the Hormuz shock hits oil and gas together, and oil drives inflation swaps.
EUR/USD fx_eurusd	Euro exchange rate (EUR=).	Control: energy is priced in dollars.
Inflation swap 1Y ils_eur_1y	A contract paying the realised euro-area inflation (HICP ex-tobacco) over one year against a fixed rate. The fixed rate = the market's expected inflation (EUCPIZ1Y=TWEB, from 2022).	Where gas shows up first in market expectations.
Inflation swap 1y1y ils_eur_1y1y	Expected inflation for the year starting one year from now (EUIL1YF1Y=R). Your file was labelled '1Y'; it is the forward.	The ECB's policy horizon: tells whether the shock is seen as persistent.
€STR OIS 1M, 3M, 1Y, 2Y; 1y1y ois_estr_*	Swaps on the ECB overnight rate (€STR). The fixed rate = the average policy rate the market expects. 1y1y (computed) = expected rate one year ahead.	The cleanest market measure of rate-hike expectations: no credit or scarcity premium.

Instrument (clean name)	What it is	Why this one
Bund yields 2Y to 30Y bund_2y ... bund_30y	Yields of the current German government bonds (Bundesbank). 2Y = 'Schatz', 10Y = 'Bund', 30Y = long bond.	The curve being studied. 2Y = policy end, 30Y = term-premium end.
Slopes and PCA slope_2s10s, slope_2s30s, slope_5s30s	Differences between long and short yields (bp). PCA splits curve moves into level, slope and curvature.	Tests the 'specific moves' part of the thesis.
Swap spread, Bund-OIS swapsprd_de5y_bp, sprd_bund2y_ois2y	5Y swap rate minus 5Y Bund; 2Y Bund minus 2Y OIS.	Separate policy repricing from flight-to-safety into Bunds.
HICP hicp_ea_idx, hicp_ea_yoy	Euro-area consumer price index (2025 = 100).	The realised inflation at the start of the chain.
Not used in headline tests	NBP (UK gas), Henry Hub (US gas), IMF monthly EU gas.	Cross-checks only. NBP is UK and in sterling; Henry Hub is the US leg of LNG trade.

4. The data: what was wrong and how it was fixed

Raw files were archived under clear names, then cleaned. Six issues mattered for the results.

Issue	Why it matters	Fix
Inflation swap mislabelled: the '1Y' file is the 1y1y forward.	Wrong label leads to wrong interpretation (near-term vs persistent inflation).	Renamed ils_eur_1y1y; the true 1Y swap was added.
HICP spliced from two index bases (fake -34% month in Dec 1999).	Year-on-year inflation is wrong for a year around the break.	Kept only data from the break on (2025 = 100 base).
Futures contract rolls. 'Front-month' series jump when the contract changes.	A roll looks like a big price move that never happened.	Roll days detected from open-interest jumps (~12 a year) and excluded.
Timing mismatch. Bundesbank yields are recorded about half a trading day before the LSEG closes used for gas, swaps and OIS.	Today's Bund move loads equally on yesterday's and today's OIS move (0.53 vs 0.49). Ignored, it fakes 'predictability'.	Daily Bund tests include the previous day's market move; the full chain is also run weekly.
Junk file (stock_data.csv): weekend rows, High below Open, unknown source.	Unreliable.	Excluded.
Duplicate file: 2-year NBP export is a copy of part of the 10-year one.	Redundant.	Excluded.

Coverage: daily from October 2014 for gas, oil, FX and the main Bunds; €STR OIS from September 2019; the 1Y inflation swap from April 2022. The war regime has 143 trading days (32 weeks).

5. How to read the numbers

Every result answers one question: when gas moves by X, how much does the rate move, and could that be luck?

Term	Meaning	Example from this study
bp per +10% TTF	Basis points the rate moves for a 10% rise in gas (1bp = 0.01%).	Bund 2Y +4.1bp per +10% TTF in the war.
Beta (sensitivity)	The slope of a regression: the average move of the rate per unit move of gas, holding oil and the euro constant.	The numbers in the tables are betas scaled to a +10% gas move.

Term	Meaning	Example from this study
p-value	Chance of seeing an effect this large if the true effect were zero. Below 0.05 = 'statistically significant'.	Bund 2Y in the war: p = 0.003, so very unlikely to be luck.
Robust (HAC) standard errors	Market data have fat tails, volatility bursts and some autocorrelation. Newey-West HAC errors stay valid under all three.	Used for every regression.
Multiple testing (Holm)	Testing 20 series raises the odds of a fluke. Holm correction raises the bar, either across all series or within a family of related ones.	Bund 2Y in the war: corrected p = 0.036 within the 13 rate series, p = 0.057 across all 20 (borderline).
Regimes	Separate periods with different market behaviour.	2014-21 pre-crisis · 2021-22 gas crisis · 2023-Feb 2026 normalisation · Iran war from 2 Mar 2026.
Daily vs weekly	Daily = more data; weekly = immune to the timing mismatch.	Results are reported at both frequencies and agree.

6. The tests, one by one

The tests run from 'what does the data look like' to 'is the effect real' to 'can it predict'. The workbook has a sheet for each.

Test	Question in plain words	What it found	Why it matters
Normality, autocorrelation, volatility clustering (Jarque-Bera, Ljung-Box, ARCH)	Do daily moves behave like textbook data?	No: fat tails, volatility bursts, some autocorrelation.	Ordinary errors would mislead; robust errors are used.
Stationarity (ADF, KPSS, Zivot-Andrews)	Do series wander (levels) or revert (changes)?	All levels wander; all changes are stable.	Analyse changes, not levels, to avoid spurious links.
Cointegration (Engle-Granger, Johansen)	Do gas and yields share a long-run level relationship?	No robust one.	Gas is a shock driver, not an anchor for the level of yields.
Transmission regressions by regime	How much does each rate move when gas moves?	Large in the war, negative in 2021-22, ~0 otherwise.	The core result.
Regime interaction and break tests (Chow, sup-Wald, CUSUM)	Did the sensitivity really change, and when?	Yes; OIS break dated 2026-03-05 to 2026-03-11.	The data find the war date on their own.
Residual diagnostics (Durbin-Watson, Breusch-Godfrey, White, RESET, VIF)	Are the regressions well behaved?	Heteroskedasticity, fat tails; some non-linearity; no harmful collinearity.	Handled with robust errors; non-linearity is a next step.
Timing tests (lead/lag, Dimson)	Are the data sources recorded at the same time?	No: Bundesbank half a day early.	Prevents false 'predictive' findings.
Mediation (block bootstrap)	Does gas move rates through inflation expectations?	Partly: ~31% of the gas effect on OIS goes via inflation swaps.	The market also prices the ECB's reaction to energy news directly.
VAR, Granger causality, impulse responses	Do gas moves today lead rate moves tomorrow?	No lead in the war or weekly.	Transmission happens on the day.
Local projections	Does the effect grow, fade or reverse over 20 days?	No further drift after day 1-2.	No momentum to trade.
Out-of-sample forecasts (Clark-West)	Would a gas model have beaten 'no change' in real time?	Not for Bunds; fragile gain for OIS in the war.	No robust forecasting edge.

Test	Question in plain words	What it found	Why it matters
HICP pass-through (lag scan)	Does gas predict realised inflation?	Yes, 6-12 months ahead.	This is where gas really predicts.
Slope comparison (2s5s … 5s30s)	Which flattener carries gas?	All flatten in the war; 2s30s largest; 2s10s and 2s5s gas-specific.	Picks the cleanest expression of the view.
Curve PCA	Which curve movement does gas cause?	Slope factor -2.8bp (p = 0.016).	Flattening: a policy-shock signature.
Event study	What happened on key dates?	War onset (2 days): 2Y +16bp, 30Y +6bp. Ceasefire: OIS 1y1y -23bp.	The regressions match the narrative.

7. Results, link by link

Link 1. Gas reaches inflation months later; oil does it at once

A +10% TTF rise has no effect on inflation in the same month (-0.01pp, not significant). It builds to +0.21pp of y/y inflation after 9 months and +0.24pp after 12. All lags together are significant ($p < 0.001$); the first six months alone are not ($p = 0.068$). Oil passes through immediately (+0.30pp the same month).

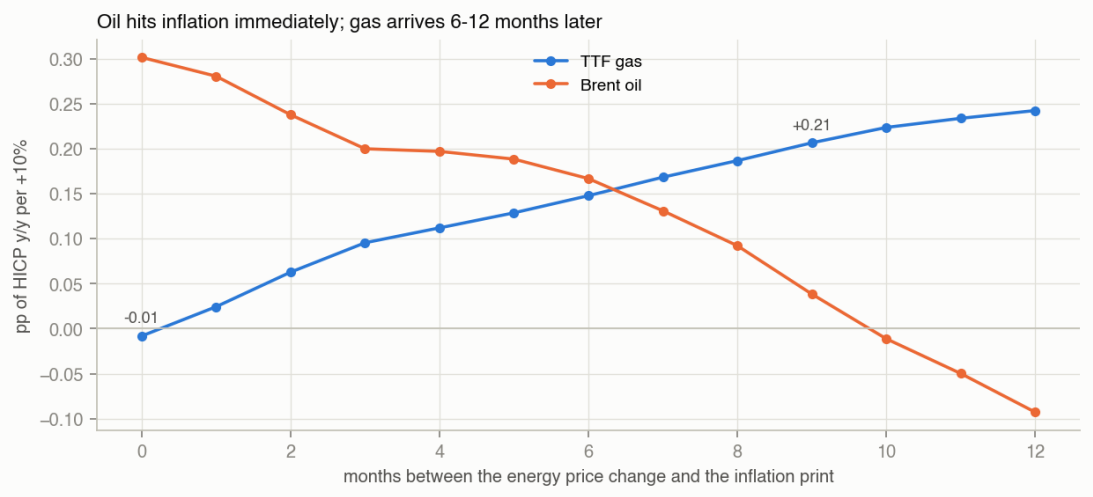

Figure 2. Effect of a +10% energy price move on euro-area inflation (y/y), by months of lag. Monthly data 2015-2026.

Links 2 to 4. In the war, gas lifts expectations, the ECB path and the front end

Inflation swaps react the same day: 1Y +6.9bp, 1y1y +1.8bp. The expected policy rate in one year rises +2.3bp (daily) to +4.8bp (weekly). The Bund 2Y rises +4.1bp daily and +3.6bp weekly; the 30Y barely moves (+0.2bp). The 2s30s slope falls 3.9bp and the weekly 5s30s 2.6bp ($p < 0.001$).

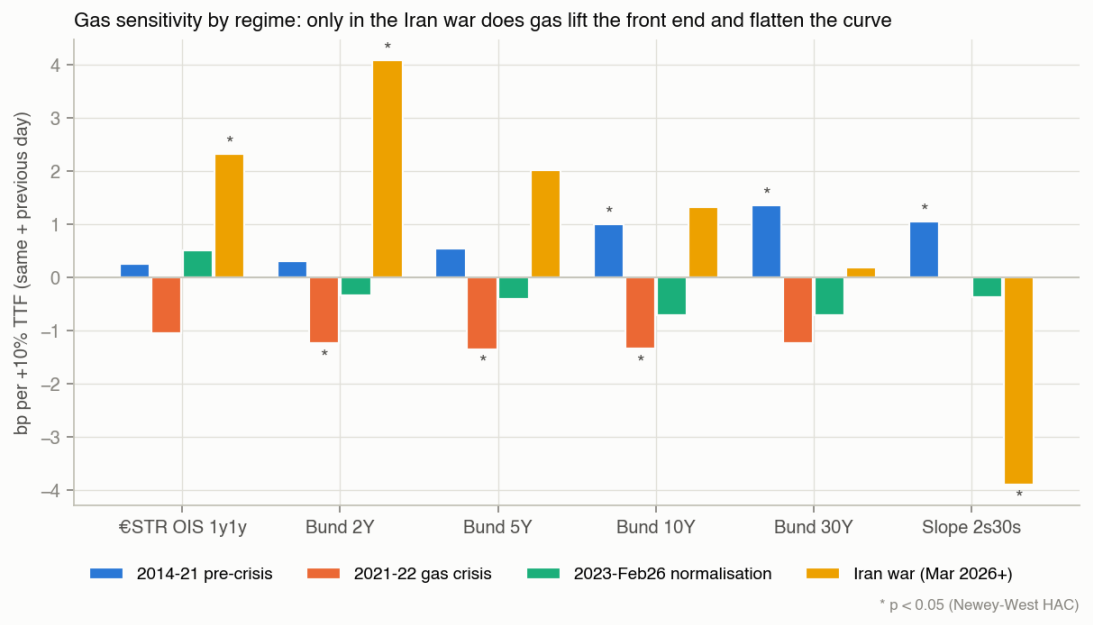

*Figure 3. Sensitivity to a +10% TTF move, by regime (daily, same day plus previous day for Bunds). * = p < 0.05.*

Which flattener carries gas?

Every slope flattened during the war because each tenor rose less than the one before it: 2Y +106bp, 10Y +78bp, 30Y +49bp. The slopes differ in how cleanly they carry gas.

Slope	War daily, bp per +10% TTF	War weekly	Brent effect (war)	War vs normal (p)	Change in war
2s5s	-2.1bp (p = 0.006)	-0.4bp (p = 0.483)	+0.2bp (p = 0.758)	0.007	25 → 14bp
2s10s	-2.8bp (p = 0.031)	-1.5bp (p = 0.092)	-0.5bp (p = 0.626)	0.041	66 → 38bp
5s10s	-0.7bp (p = 0.285)	-1.1bp (p = 0.008)	-0.7bp (p = 0.203)	0.305	41 → 24bp
10s30s	-1.1bp (p = 0.071)	-1.5bp (p < 0.001)	-1.7bp (p = 0.012)	0.037	67 → 38bp
2s30s	-3.9bp (p = 0.015)	-3.0bp (p = 0.009)	-2.2bp (p = 0.115)	0.018	133 → 76bp
5s30s	-1.8bp (p = 0.072)	-2.6bp (p < 0.001)	-2.4bp (p = 0.016)	0.068	108 → 62bp

- **2s30s**: the largest and most robust gas flattener, significant both daily and weekly. It also flattens on oil, so it is an energy trade more than a pure gas trade.
- **2s10s**: significant daily, borderline weekly, and no oil effect: the cleanest gas-to-ECB expression.
- **2s5s**: the sharpest same-day reaction (survives correction within the curve family, p = 0.045), but it fades within the week as the 5Y catches up with the 2Y.
- **5s30s, 10s30s**: the long end flattens on weekly data, driven by energy in general (oil as much as gas).
- **Regime**: before 2021 gas slightly *steepened* the curve, because the front end was pinned at the lower bound and only long yields could move. In 2021-22 slopes did not move; the whole curve shifted.

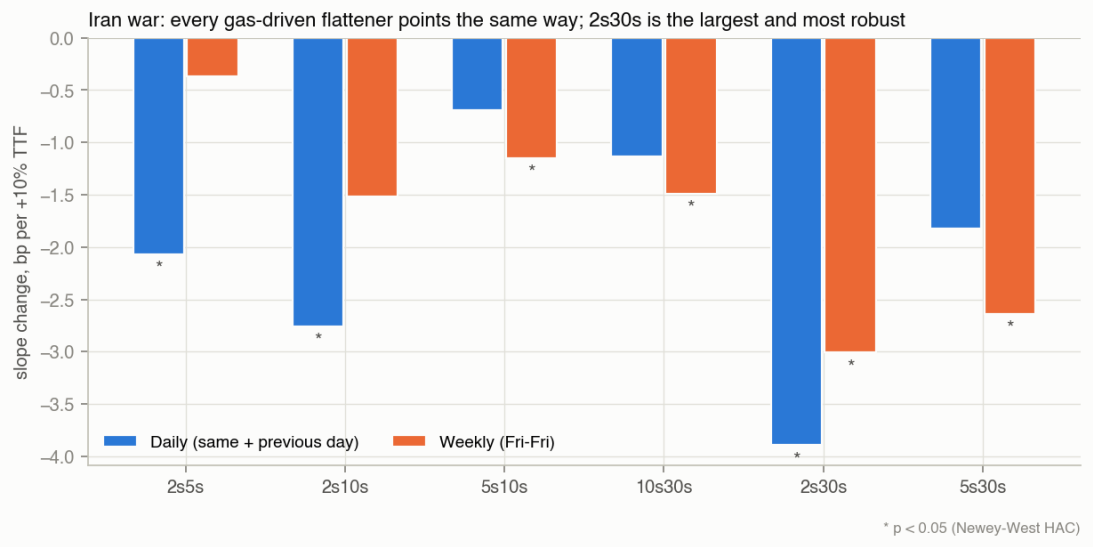

*Figure 4. Slope change per +10% TTF in the war, daily vs weekly. * = p < 0.05.*

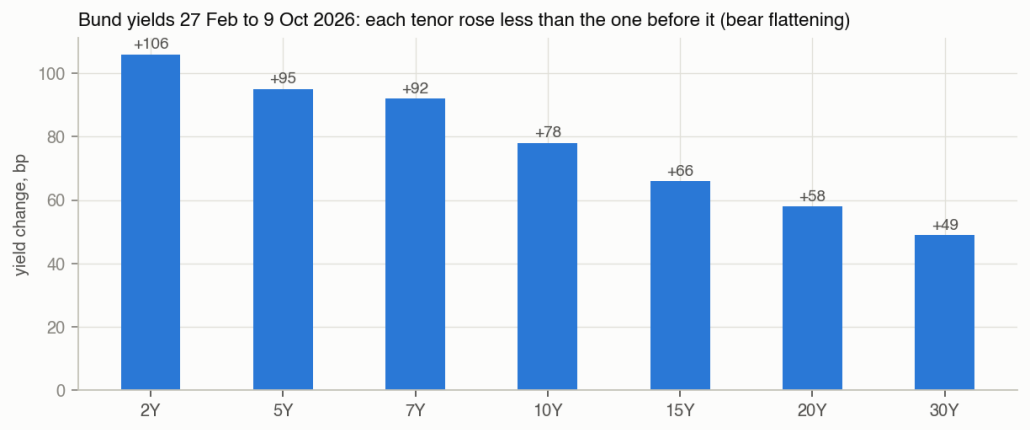

Figure 5. Change in Bund yields by tenor, 27 February to 9 October 2026.

How much goes through inflation expectations?

In the war, about 31% of gas's daily effect on the expected ECB rate runs through the 1y1y inflation swap; the rest is priced directly. At weekly frequency, the indirect path through inflation swaps and OIS to the Bund 2Y totals +3.2bp per +10% gas, and each 1bp of OIS 1y1y passes 0.71bp into the 2Y Bund.

Does the effect persist or predict?

The response happens on the day (two days for Bunds, because of the timing mismatch) and then stays flat or fades: no drift that a trader could exploit.

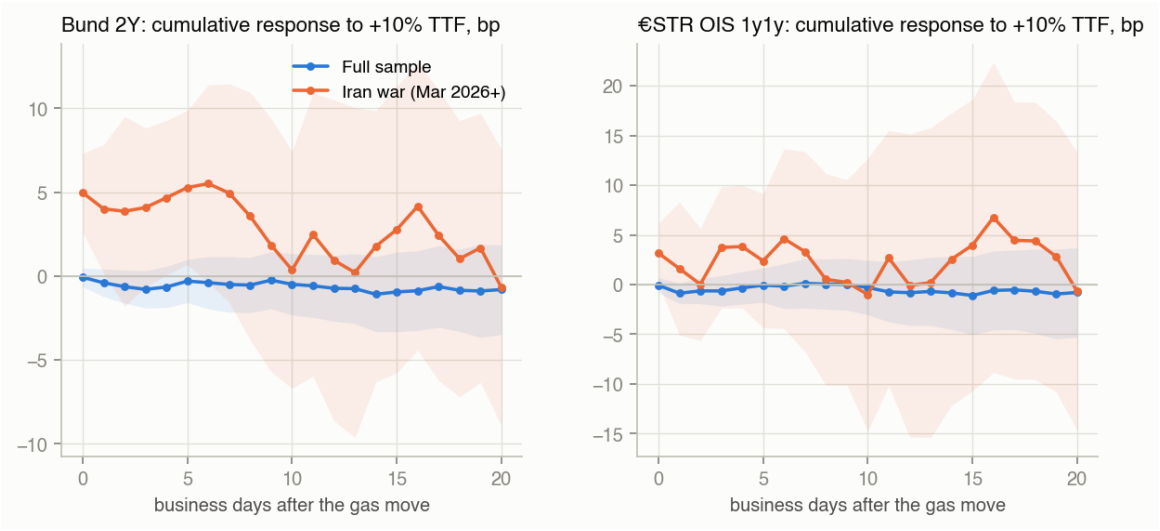

Figure 6. Cumulative response to a +10% TTF move over 20 business days (local projections, 95% bands).

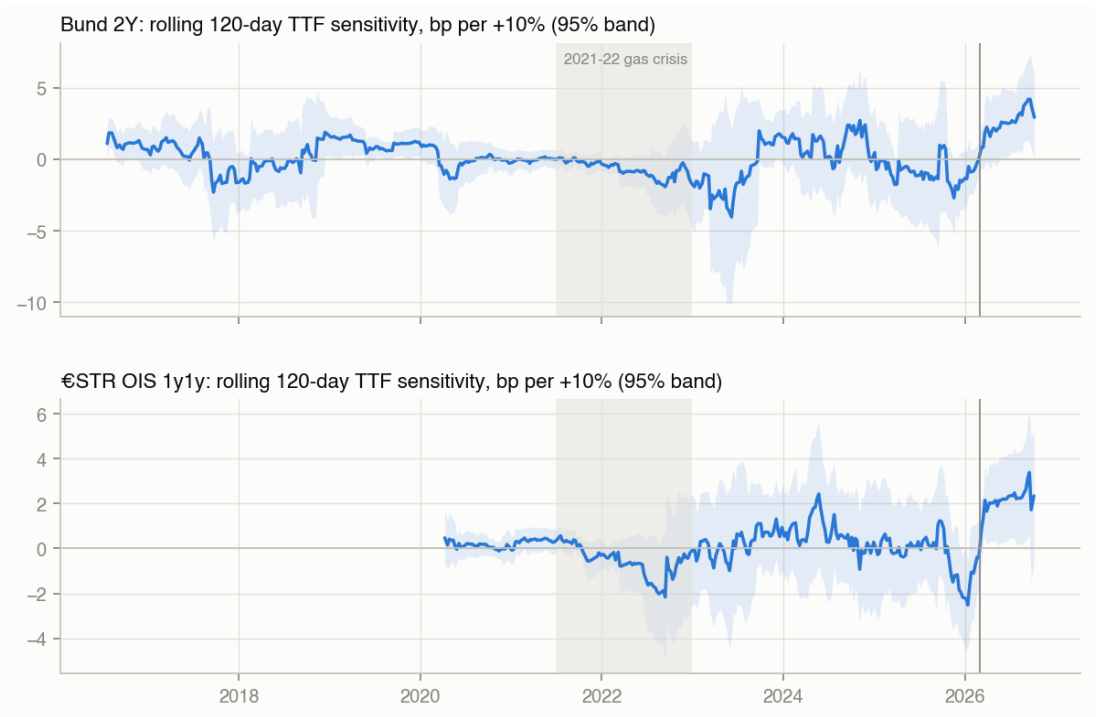

Figure 7. Rolling 120-day sensitivity of the Bund 2Y and OIS 1y1y to gas. Shaded: 2021-22 gas crisis. Vertical line: war onset.

8. What it means

The sign of the gas-rates link is set by the ECB's perceived reaction

In 2021-22 higher gas meant *lower* rates: Bund 2Y -1.2bp and OIS 1y1y -4.0bp (weekly) per +10% gas. Markets saw gas as a recession risk, and the ECB was calling inflation transitory. In 2026 the ECB is seen as reactive (it hiked in June and September), so gas became a hawkish signal. Gas itself did not change; the expected policy response did.

Gas is priced as a policy shock, not a long-run inflation shock

The short end moves, the long end does not, and the 1y1y inflation swap moves far less than the 1Y. Markets read the gas spike as a near-term price shock that will trigger hikes, not as a permanent rise in inflation. That is exactly the bear-flattening signature.

Gas explains curve moves; it does not forecast them

Gas news is public and priced within a day or two, so there is no tradable lead. The predictive content is macro: today's gas move tells you about inflation prints 6-12 months ahead, which the ECB will react to at future meetings.

Oil matters even more

Brent's effect on the expected ECB rate is about 5x gas's (+11.4bp vs +2.3bp per +10%). In this crisis the two move together, so their roles are only partly separable: depending on the ordering assumed, gas explains between 2% and 40% of the variance of the expected ECB rate. The gas effect on the Bund 2Y survives controlling for oil.

> **Practical takeaway.** Use gas as a regime-dependent front-end and curve-shape factor. Monitor its rolling sensitivity (Figure 7): a fall toward zero or below would signal that markets again see gas as a growth risk rather than an ECB trigger.

9. Limits and how to strengthen the study

- **One episode, short sample.** 143 daily / 32 weekly observations: enough to reject a zero effect, not to pin the size down precisely.
- **Co-movement is not full causality.** War headlines move gas, oil and rates together. A cleaner design would use LNG-specific outage news or intraday windows around gas moves.
- **Non-linearity.** Model checks (RESET) suggest big gas days matter more than proportionally. A threshold model is a natural next step.
- **Missing data worth adding:** HICP energy sub-index, 5y5y inflation swap (long-run anchoring), a volatility index (VSTOXX) for risk-off days, and a constant-maturity (zero-coupon) Bund curve.

10. Glossary

Term	Definition
Basis point (bp)	0.01 percentage point. A yield moving from 3.00% to 3.04% has risen 4bp.
Bear flattening	Yields rise (bear) and short yields rise more than long ones, so the curve flattens.
2s5s, 2s10s, 2s30s ...	Slope between two maturities: e.g. 2s10s = 10-year minus 2-year yield, in bp. A falling slope = flattening.
TTF	Title Transfer Facility, the Dutch gas hub that serves as Europe's gas price benchmark.
Front-month / continuation	The futures contract closest to delivery; a 'continuation' series rolls to the next contract when one expires.
HICP / HICPxT	Harmonised Index of Consumer Prices (euro-area inflation); xT = excluding tobacco, the index inflation swaps pay on.
Inflation swap (ILS)	A contract exchanging realised inflation for a fixed rate; the fixed rate is the market's inflation expectation.
1y1y forward	The one-year rate starting one year from now.
€STR / OIS	€STR is the ECB's overnight rate; an overnight index swap's fixed rate is the market's expected average €STR over its life.
Schatz / Bobl / Bund	German government bonds of 2, 5 and 10+ years.
Term premium	Extra yield investors demand to hold long bonds rather than roll short ones.
Swap spread	Swap rate minus government bond yield; measures the safety/scarcity value of Bunds.
Regression beta	The average move in one variable per unit move in another, holding controls constant.
p-value	Probability of an effect this large if the true effect were zero.
HAC (Newey-West)	Standard errors that stay valid with heteroskedasticity and autocorrelation.
Holm correction	Adjusts p-values when many hypotheses are tested at once.
Mediation	Splits an effect into the part that runs through an intermediate variable and the rest.
Granger causality	Whether past values of one series help predict another.
Local projection	Regression of the cumulative future change on today's shock, horizon by horizon.
sup-Wald (Quandt-Andrews)	Searches every possible date for a structural break and tests the strongest.
PCA	Splits curve moves into independent factors: level, slope, curvature.
Clark-West test	Compares the forecast accuracy of a model with a simpler benchmark it nests.
